

BUSINESS OVERVIEW

Settle

Family money, sorted.

A shared family wallet for Nigerian remittances - designed to make sending, requesting and settling money feel as familiar as a family chat.

**One shared wallet.
Clear balances in naira.
Crypto stays under the hood.**

NAIRA-FIRST EXPERIENCE

FAMILY-LED MONEY
FLOWS

EMBEDDED WALLET UX

Project context

Settle is a Monad Metropolis Track 02 consumer payments project by Savitura. The current repository is a functional hackathon MVP and demonstration environment; the consumer brand is still a codename.

01 THE OPPORTUNITY

Remittance is only half the family money problem

The project starts from a simple observation: money sent to family does not stop being a remittance when it arrives. It becomes rent, school fees, electricity, groceries, fuel and many small reimbursements that still need to be coordinated.

Cost and friction

The project brief identifies traditional remittance fees of roughly 5-8%. Small, frequent support payments become disproportionately expensive.

Fragmented coordination

Families often manage requests, reminders and confirmations across chats, bank apps and informal records. Nobody has one shared view.

Poor visibility

A transfer receipt proves money moved, but it does not show the family's current balances, open requests or who has settled what.

Crypto complexity

Wallet addresses, seed phrases, gas and approvals create a steep learning curve for people who simply want to send naira to someone they trust.

The job to be done

Help a family member move and coordinate money with trusted relatives in seconds, while keeping the experience understandable, accountable and locally relevant.

Primary users

Sender / supporter	A diaspora or local family member funding household needs and reimbursing relatives.
Recipient / household manager	A trusted relative managing recurring expenses and needing clear access to funds.
Family group	A small circle of up to three members coordinating shared obligations and requests.

02 THE PRODUCT

A familiar layer over modern payment rails

Settle organizes family money around a shared wallet and everyday actions. Users sign in with email or phone; an embedded wallet is created behind the scenes. The main experience speaks in naira and uses human actions - Send money, Request and Settle up - instead of blockchain terminology.

STEP	USER ACTION	VALUE CREATED
1	Create or join	Start a named family wallet and invite relatives with a six-character code or link.
2	See the family position	View the group balance, individual member balances, pending requests and recent activity.
3	Move or ask for money	Send a naira amount to a member, or create a request with a note for context.
4	Close the loop	Pay a pending request, update balances and retain a readable activity trail.
5	Cash out	The intended product supports bank or mobile-money delivery; the MVP presents this as a clearly labeled demo flow.

Why the proposition is differentiated

Family context, not a generic wallet

Groups, names, notes and requests turn transfers into an understandable household ledger.

Local mental model

Naira amounts lead the interface; stablecoin conversion is an implementation detail.

Low-friction access

Email or phone sign-in removes the separate connect-wallet and seed-phrase experience.

Design principle

The value is not 'crypto for families.' The value is a coherent family-money experience whose settlement layer can be faster and cheaper than traditional rails.

03 BUSINESS OVERVIEW

Where the business can create and capture value

The repository defines the user proposition and MVP, not a finalized commercial model. The following business model is therefore a logical product direction, not a claim about currently implemented pricing or partnerships.

Customer segments	Nigerian families receiving or coordinating support; diaspora senders; small trusted family groups.
Core value	Lower-friction transfers plus a shared record of balances, requests and settlements.
Channels	Mobile web first; family invitations through WhatsApp, SMS or email; diaspora and community partnerships.
Potential revenue	Transparent transfer or cash-out fee; FX spread where permitted; premium family tools; partner revenue from regulated payment providers.
Key partners	Licensed remittance and payments providers, Nigerian banking/off-ramp partners, identity and wallet infrastructure, stablecoin liquidity partners.
Key costs	Compliance, payment and off-ramp fees, customer support, fraud controls, infrastructure, liquidity and user acquisition.

A plausible growth loop

Success metrics for validation

Activation	Share of signed-in users who create/join a wallet and complete a first money action.	Household adoption	Invite acceptance, members per active wallet and time to first joined relative.
Repeat utility	Monthly active family wallets, requests created, settlement rate and transfers per wallet.	Trust and economics	Failed transactions, support contacts, cash-out completion, fraud loss and contribution margin.

04 EXECUTION VIEW

What exists now - and what must come next

The current build is best understood as a product-validation MVP. It proves the interaction model and stores the core family-wallet records, but it does not yet represent a production remittance service.

Working MVP capability	Privy email/phone authentication and embedded wallet creation; family wallet creation and invite flow; member balances; send, request and settle-up flows; activity history; Neon/Postgres persistence; a one-click Lagos demo scenario.
Demonstration behavior	The exchange rate is fixed in code at NGN 1,580 per USDC; transaction hashes are generated locally; sending updates database balances; cash-out is explicitly mocked; chain configuration targets Monad Testnet.
Production gap	Real stablecoin transfers, live rates, fiat funding and cash-out, regulated partners, reconciliation, security hardening, customer support, compliance and operational controls remain to be built.

Recommended path to market

NOW	Validate the family workflow	Test comprehension, invite conversion, request behavior and whether a shared ledger improves trust.
NEXT	Connect regulated money movement	Integrate live stablecoin settlement, funding and Nigerian bank/mobile-money cash-out through licensed partners.
THEN	Harden operations	Add identity checks, transaction monitoring, limits, reconciliation, disputes, support tooling and security reviews.
SCALE	Expand the family financial layer	Introduce recurring contributions, goals, bill allocation and additional corridors only after the core loop is trusted.

Principal risks

Regulatory classification and licensing; off-ramp reliability; fraud and account takeover; stablecoin and FX exposure; liquidity management; privacy across family groups; trust loss from failed or delayed transfers. These are central business requirements, not later-stage polish.

05 SUMMARY

The ambition

Settle aims to become the trusted coordination layer for family money across borders: easy enough for everyday use, transparent enough for shared obligations, and efficient enough for frequent small transfers.

Why it matters

The product reframes remittance from a single transaction into an ongoing family relationship. By combining money movement with requests, balances and shared history, Settle can solve the coordination problem that begins after money is sent.

Why the technology fits

Embedded wallets can remove crypto onboarding friction, while a high-throughput, low-fee network can support frequent low-value transactions. Stablecoin settlement is useful only insofar as the user experience remains simple, naira-first and reliable.

What must be proven

The next evidence should be behavioral and operational: families repeatedly use the shared workflow; invites convert; requests are settled; real cash-in and cash-out work reliably; and the model can comply with applicable regulation while producing sustainable unit economics.

SETTLE IN ONE SENTENCE

A shared family wallet for Nigerian remittances - send, request and settle up in naira, while crypto stays under the hood.

Basis and links

This document was derived from the repository README, project submission blurb, user-interface copy, database schema and implemented send/request/settlement flows. Statements about fees, revenue, partnerships and roadmap are presented as assumptions or recommended directions where they are not implemented.
